

UM3758 Series

Tri-State Programmable Encoder/Decoder

Features

- Single-Chip CMOS construction
- Single-Chip **encoder/decoder** selected by jump wire
- Wide operating voltage range : $V_{DD} = 3$ to 12 Volts
Built-in RC oscillator (can use 5 % resistor)
- Easy interface with RF, **Infrared(IR)** and **Ultrasonic** transmission media
- Tri-state(0, 1, open) address codes, some of address

codes used as data **codes** or as internal addresses by mask **option**

- Internal address **code** is 18-bit, ie $3^{18} = 387,428,489$ different **codes** at most
- Decoder has 8-bit latch data
- Series IC for various applications
- **UM3758-120A** pin out compatible to UM3750

General Description

The UM3758 series are single-chip programmable encoder/decoder ICs fabricated in CMOS structure for low power consumption. They are enhanced for new stage encoder/decoder ICs to provide many more combinations for higher security.

Most combinations are achieved by **UM3758-180A**, providing $3^{18} = 387,420,489$ combinations. Some ICs of this series provide 4 to 8 data bits for controlling.

According to the following information, The internal address bits, 18 bits/24-pin and 12 bits/18-pin package, can be assigned by customer in advance for much higher security and confidentiality. Whenever the address codes of transmitter transmits, the receiver will check the address codes with his own and the successive two matched address codes will generate a low pulse. If there were any data bits, the receiver will latch these data bits at the corresponding pins for controlling.

Pin Configurations

Pin Configurations (Continued)

Absolute Maximum Ratings*

Power Supply Voltage -0.3V to 11V
 Operating Temperature -20°C to 70°C
 Storage Temperature (Tstg) -55°C to 150°C
 Apply Voltage on any Pin
 $V_{SS} - 0.3 < V_{IN} < V_{DD} + 0.3$

*Comments

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only. Functional Operation of this device at these or any other conditions above those indicated in the operational sections of this specification is not implied and exposure to absolute

DC Electrical Characteristics

($T_A = 25^\circ\text{C}$, $V_{DD} = 9\text{ Volts}$, $V_{SS} = 0\text{V}$ unless otherwise specified)

24	18	20	VDD	The positive power supply of UM3756

Functional Description

General

The operating mode of the UM3756 series is **controlled** by the 'MODE' pin. When the 'MODE' pin is connected to VDD the circuit will automatically switch to encoder mode, then **"TX/RX OUT"** pin **acts** as data out pin and **"RX INP"** pin act as an idle pin. When 'MODE' pin is connected to Vss the circuit will switch to decoder mode, then **"TX/RX OUT"** pin will switch to LOW if comparison is **OK**, otherwise this pin will keep HIGH, and **"RX/INP"** receives waveform from detect circuit.

Encoder Mode

The encoder mode is selected by connecting "MODE" pin to VDD.

The transmit sequence is initiated by the power **con**-
nection and continuously transmits till power down.
Each transmitted address bit is encoded into address

pulses (see Fig. 1). A logic zero is encoded as **two** consecutive long pulses, a logic one as **two con**-
secutive short pulses and an open as a long pulse
followed by a short pulse. **Each** transmitted data **bit**
is encoded into logic **zero** or one and the data pulse
is the **same** as the address pulse (see Fig. 1), ie.,
the state of data pin is either one or **zero**. The **data**
is one **when** connected to VDD or open and **zero** **when**
connected to Vss.

The **UM3758-180A** samples the 18 **bit** tri-state address
and **encodes** this parallel address data for **trans**-
mitting. These 16 address pins may **be** in either of
three states (0, 1, open) allowing $3^{18} = 387,420,489$
possible **combinations** then **the UM3758-120A** provides
12-bit address and **allows** $3^{12} = 531,441$ possible **com**-
binations.

The **UM3758-108A/B** and **UM3758-084A/B** provide address
bits and data bits, as described in Table 1.

Part Number	Address Bits	Address Combinations	Data Bits	Data Combinations
UM3758-108A/ B/AM/BM	10	59,049	8	256
UM3758-084A/ B/AM/BM	a	6,561	4	16

Table 1

Decoder Mode

The decoder mode is selected by connecting "MODE" pin
to vss.

The decoder receives the serial data from the detect
circuit and outputs the comparison result or data, if
it is valid. The received data may **include two types**
— without data and with data.

For decoder without data ICs, such as **UM3758-180A** and
UM3758-120A the address word is examined bit by bit as
received; if two successive address words **match** the
address bis of **decoder**, the **"TX/RX OUT"** pin will
switch to LOW and **two** successive **unmatched** address
words will **cause** **"TX/RX OUT"** pin to return to HIGH
(see Fig. 3-1).

For decoder with data IC, such as **UM3758-108A/B** and
UM3758-084A/B, the address word with data word are
examined bit by bi as received. The first 10 bits

(ex. **UM3758-108A/B**) are assumed to be address bi.
If the address bits **match** the address bits from
detect circuit, the next eight data bits are stored
and **matched** to the last valid data stored. When the
second word with data is received, the address bis
must **match** again, and if it does, the data bits are
checked against the previous stored data biis. If
the two words (eight bits data **each**) of data **match**,
the data is transferred to the output data pins (**D1**,
D2 to **D8**). If the decoder is momentary type, the data
pins will latch the data till the **"TX/RX OUT"** pin
switches to HIGH; for **latch** decoder, the data pins
will latch the data till the next valid data appears
(see Fig. 3-2). Although the address bits **are** **tri**-
state (0, 1, open), the data information must be
either one or **zero**. An open state will be **decoded as**
a logic one. The above table (Table 1) also describes
these (decoder with data).
